**XML Schema, XPath, and XQuery**

Juliana Freire

- some slides by David Koop, 2007
- some material taken from http://www.w3.org/TR/xmlschema-0/

### XML Review

- Tagged, tree-structured data stored as a text file

```xml
<list title="authors">
  <person>
    <initials>H.K.</initials> <surname>Gershenfeld</surname>
  </person>
  <person>
    <initials>R.J.</initials> <surname>Hershberger</surname>
  </person>
  <person>
    <initials>T.B.</initials> <surname>Shows</surname>
  </person>
  ...
</list>
```

- Power comes from related technologies: schemas, query languages, protocols, app.-specific dialects

### XML Data Model Visualized

#### Generic XML Processing Model

- XML Information Set
  - per-character, per-entity model of XML document

![Diagram of XML Information Set and Processing Model]

- Document Parser
  - Expand entity references
  - Check well-formedness

- Document Validator
  - Validate data
  - Add type annotations
  - Insert default values

- Application/Storage System
  - XML Infoset
  - XML Schema
  - DTD or XML Schema

- XML APIs and Relational Analogues

<table>
<thead>
<tr>
<th>XSLT, XQuery, XPath</th>
<th>SQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOM API</td>
<td>JDBC/ODBC</td>
</tr>
<tr>
<td>SAX API</td>
<td>Relational Schema / SQL</td>
</tr>
<tr>
<td>XML Schema</td>
<td>Relational Data Model</td>
</tr>
<tr>
<td>XPath Data Model/ XML Infoset</td>
<td>Relational Database</td>
</tr>
</tbody>
</table>

### Parsing

- XML Document » XML Information Set
- Checks well-formedness
- Doesn’t check that information conforms to any structural rules
- Doesn’t check that data matches expected type
Validation

- XML Info Set + XML Schema »
  Post-Schema Validation Info Set (PSVI)
- PSVI includes type information
- An Info Set passes validation if it conforms to the schema
- Checks for legal tag & attributes, proper nesting & ordering of tags, and proper types
- Why do we care?
  Query optimization, hand editing, storage, transferring between applications, mapping to programming languages

XML Schema

- Defines:
  - vocabulary (element and attribute names)
  - content model (relationships and structure)
  - data types
- Written in XML
- Often uses namespace abbreviated as xs or xsd
- Namespace declaration:
  <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">

XML Schema Example

```xml
<?xml version="1.0"?>
<purchaseOrder orderDate="2007-10-16">
  <shipTo country="US">
    <name>Alice Smith</name>
    <street>123 Maple Street</street>
    <city>Mill Valley</city>
    <state>CA</state>
    <zip>90952</zip>
  </shipTo>
  <billTo country="US">
    <name>Bob Smith</name>
    <street>8 Oak Avenue</street>
    <city>Old Town</city>
    <state>PA</state>
    <zip>95819</zip>
  </billTo>
  <item partNum="926-AA">
    <product>Baby Monitor</product>
    <quantity>1</quantity>
    <USPrice>148.95</USPrice>
    <comment>Confirm this is electric</comment>
  </item>
  <item partNum="872-AA">
    <product>Lawnmower</product>
    <quantity>1</quantity>
    <USPrice>39.98</USPrice>
    <shipDate>1999-05-21</shipDate>
  </item>
</purchaseOrder>
```

XML Schema Simple Types

- XML Schema defines primitive types
- Examples: string, boolean, int, boolean, date, anyType, anySimpleType
- anyType allows any type, anySimpleType allows any primitive type
- Examples:
  XML: <comment>Hurry, my lawn is going wild!</comment>
  Schema: <xsd:element name="comment" type="xsd:string"/>
  XML: <shipDate>1999-05-21</shipDate>
  Schema: <xsd:element name="shipDate" type="xsd:date"/>

XML Schema Header

- Schema uses a namespace
- Annotations can be inlined into the schema for documentation
  Example:
  <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <xsd:documentation xml:lang="en">
      Purchase order schema for Example.com.
      Copyright 2000 Example.com. All rights reserved.
    </xsd:documentation>
    <xsd:annotation>
      ...
    </xsd:annotation>
  </xsd:schema>

XML Schema Types

- Simple and complex element types
  Simple: <shipDate>2007-10-16</shipDate>
  Complex: <purchaseOrder orderDate="2007-10-15">
    ...
  </purchaseOrder>
- An element with attributes is always complex
- Attributes are unordered
- Can restrict attribute or element values
XML Schema Complex Types

- XML Schema supports nested types
- Can choose to reference type definition or use an anonymous complex type
- Example:
  
  XML:
  
  ```xml
  <purchaseOrder orderDate="2007-10-15">
    <shipTo>...</shipTo>...
  </purchaseOrder>
  ```
  
  Schema (Reference):
  
  ```xml
  <xsd:element name="purchaseOrder" type="PurchaseOrderType"/>
  <xsd:complexType name="PurchaseOrderType">
    <xsd:sequence>
      <xsd:element name="shipTo" type="USAddress"/>
      ...
    </xsd:sequence>
    <xsd:attribute name='orderDate' type=xsd:date/>
  </xsd:complexType>
  ```

Number of Occurrences

- Number of times an element appears in a document: minOccurs and maxOccurs
- Default values:
  - minOccurs: 1
  - maxOccurs: 1

  ```xml
  <xsd:element name="item" minOccurs="0" maxOccurs="unbounded"/>
  ```

  maxOccurs can be unbounded, allowing an unlimited number of those elements

XML Schema Restrictions

- We can even enumerate all possible values:

  ```xml
  <xsd:simpleType name="USState">
    <xsd:restriction base="xsd:string">
      <xsd:enumeration value="AK"/>
      <xsd:enumeration value="AL"/>
      <xsd:enumeration value="AR"/>
      <!-- and so on ... -->
    </xsd:restriction>
  </xsd:simpleType>
  ```

XML Schema Grouping

- Order of nodes matters in XML
- Elements of a complex type definition inside `<xsd:sequence>` must appear in XML documents in that order
- If you don't care about order, use `<xsd:all>...</xsd:all>`
- If you want the schema to include one type of element from a given group, use `<xsd:choice>...</xsd:choice>` inside `<xsd:sequence> or `<xsd:all>`

XML Schema Restrictions

- Define restrictions for elements/attributes

  ```xml
  <xsd:element name="quantity">
    <xsd:simpleType>
      <xsd:restriction base="xsd:positiveInteger">
        <xsd:maxExclusive value="100"/>
      </xsd:restriction>
    </xsd:simpleType>
  </xsd:element>
  ```

  ```xml
  <xsd:simpleType name="SKU">
    <xsd:restriction base="xsd:string">
      <xsd:pattern value="\d{3}-[A-Z]{2}\"/>
    </xsd:restriction>
  </xsd:simpleType>
  ```
Query Languages

- XPath 2.0
  - Common language for navigation, selection, extraction
  - Used in XSLT, XQuery, XPath, XForms, et al

- XSLT 2.0: XML ⇒ XML, HTML, Text
  - Loosely-typed scripting language
  - Format XML in HTML for display in browser
  - Must be highly tolerant of variability/errs in data

- XQuery 1.0: XML ⇒ XML
  - Strongly-typed query language
  - Large-scale database access
  - Must guarantee safety/correctness of operations on data

- Over time, XSLT & XQuery may both serve needs of many application domains

Common Querying Tasks

- Filter, select XML values
  - Navigation, selection, extraction

- Merge, integrate values from multiple XML sources
  - Joins, aggregation

- Transform XML values from one schema to another
  - XML construction

- Programmatic interfaces (DOM/SAX) specify how
- Query languages specify what, not how
- Provide abstractions for common tasks
- Easier than programmatic interfaces

Query Processing Model

- Other models possible

<table>
<thead>
<tr>
<th>XML Document(s)</th>
<th>XML Schema(s)</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

XPath 2.0

Data Model

Parser

Validator

Query

Evaluator

Instance

Application

(May) type check query

Evaluates query on data model instance
XPath

- Syntax for navigating XML
- Looks similar to file paths
- Used by XML Schema, XSLT, XQuery
- Searches by structure and text
- Guarantees same syntactic expression has same semantics
- Navigation, selection, value extraction
- Arithmetic, logical, comparison expressions

XPath Syntax

- /node-name == /child::node-name
- Relative paths work as expected
  - /imdb == /imdb/show/title/..
  - /imdb == /imdb/./.
  - // == descendant-or-self
- Predicate tests (filter node set)
  - [Inside brackets]
  - Prefix attributes by @
  - //show[@title = "Seinfeld"] == //show[./title/text() = "Seinfeld"]
- Standard comparisons:
  - //show[@year > 2005]
  - Comparisons based on ordering:
    - //surgery[/anesthesia[1] before //incision[1]]

XPath Functions

- Library of functions available
- Use fn namespace
- Ordering: fn::position, fn::first, fn::last
- String Operations: fn::substring, fn::starts-with, fn::matches
- Numeric Operations: fn::abs, fn::floor
- Many more:
  - http://www.w3.org/TR/xpath-functions/
  - http://www.w3schools.com/xpath/xpath_functions.asp

Variability in XML Data

- Problem: Replication or absence of XML values
  - Demands flexible semantics for selection
- Selection:
  - //show[year >= 2000]
    - Explicit expression:
      - //show[some $v in ./child::year satisfies data($v) ge 2000]
      - matches all shows that contain at least one year child whose numeric content is greater than 2000
- Existence/absence of value:
  - //show/reviewer[following-sibling::rating]
    - Explicit expression:
      - //show/reviewer[not empty(.//following-sibling::rating)]
Variability in Schemas

- Documents may contain fragments with strongly typed values and un-typed text
- Demands flexible, but consistent semantics
  <book isbn="ISBN 10-111">  
  <price>45.50</price>  
  </book>
- For un-typed text, permissive correction from PCDATA to typed values
  /book/price * 0.07 SUCCEEDS!
- For typed values, strict interpretation of typed values and type error is fatal
  /book/@isbn * 0.07 FAILS!

Beyond XPath 2.0

Limitations
- Constructing new XML
- Recursive processing of recursive XML data

Differences between XSLT & XQuery
- Safety: XQuery enforces input & output types
  - Compositionalty:
    - XQuery maps XML to XML, XSLT maps XML to anything
    - Important feature for XML publishing

XQuery 1.0

- Functional, strongly typed query language
- XQuery 1.0 = XPath 2.0 + ...
  - A few more expressions
  - FLWOR
  - Sort-by
  - XML construction (Transformation)
  - Operators on types (Compile & run-time type tests)
- User-defined functions
  - Modularize large queries
  - Process recursive data
- Strong typing
  - Guarantees result value conforms to output type
  - Enforced statically or dynamically

XQuery FLWOR

SQL:
SELECT <attribute list>
FROM <set of tables>
WHERE <set of conditions>
ORDER BY <attribute list>

XQuery: FOR-LET-WHERE-ORDERBY-RETURN

- FOR/LET Clauses
- WHERE Clause
- ORDERBY/RETURN Clause

Instance of XQuery data model

XQuery: Example

For each actor, return box office receipts of films in which they starred in past 2 years

let $imdb := document("www.imdb.com/imdb.xml")
for $actor in $imdb/actor
let $films :=
    $imdb/show[box_office and @year >= 2000 
    and $actor/name = .]/actor[@role="star"]/name
join
return
    <receipts>
    { $actor }
    <total> { sum($films/box_office) } </total>
</receipts>

XQuery

- FOR $x in expr -- binds $x to each value in the list expr
- LET $x := expr -- binds $x to the entire list expr
  - Useful for common subexpressions and for aggregations
FOR vs. LET

Returns:
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>

FOR $x$ IN document("imdb.xml")//show
RETURN <result> $x$ </result>

LET $x$ := document("imdb.xml")//show
RETURN <result> $x$ </result>

Returns:
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>
<result> <show>...</show> <result>

FOR $x$ IN //show WHERE EVERY $a$ IN $x$ SATISFIES contains($a$, "Term")
OR contains($a$, "T3")
RETURN $x$/title

Aggregates

Find movies whose box office proceeds are larger than average:

LET $a$ := avg(document("imdb.xml")//box_office)
FOR $s$ in document("imdb.xml")//show
WHERE $s//box_office > $a$
RETURN $s$

Collections in XQuery

- Ordered and unordered collections
  - /bib/book/author = an ordered collection
  - Distinct(/bib/book/author) = an unordered collection
- LET $s$ := /imdb/show → $s$ is a collection
- $s$/title → a collection (several titles...)

RETURNS: $s$/title </result>

If-Then-Else

FOR $s$ IN //show
ORDERBY $s$/year
RETURN <show>
  $s$/title,
  IF $s$/box_office THEN <movie> ... </movie> ELSE <tv_show> ... </tv_show>
</show>

Existential Quantifiers

FOR $s$ IN //show
WHERE SOME $a$ IN $s$/aka SATISFIES contains($a$, "Term")
OR contains($p$, "T3")
RETURN $s$/title

Universal Quantifiers

FOR $s$ IN //show
WHERE EVERY $a$ IN $s$/aka SATISFIES contains($a$, "Term")
RETURN $s$/title
XML Transformation

- User-defined functions
  - Signatures specify types of arguments & return values
  - Types enforced statically or dynamically
  - Same expressiveness as XSLT templates + parameters

define function show2movie(element show $show)
  returns element movie?
  { // Convert a show (that is a movie) to a movie
    if ($show/@year) then <movie> { $show/* } </movie>
  } else ()
} let $imdb := document("www.imdb.com/imdb.xml")
return <movies>
  for $show in $imdb/show return show2movie($show)
</movies>

Change Question

Are the following queries equivalent?

A. FOR $show IN document("www.imdb.com/imdb.xml")//show,
  WHERE $show/@year >= 2002
  RETURN <show> <t>$show/title</t> <r>$show/review</r> </show>

B. FOR $show IN document("www.imdb.com/imdb.xml")//show
  WHERE $show/@year >= 2002
  RETURN <show> <t>$show/title</t> <r>$show/review</r> </show>

Safety

- Shared schema (S_{shared}) is contract between producers & consumers
- Producer writes query to transform input data into output data
  \( D_{input} : S_{input} \Rightarrow Q_{producer} \Rightarrow D_{output} : S_{output} \)
- Static Type Checking takes \( S_{input} & Q_{producer} \)
- Infers \( S_{output} \) : schema of output data
- Checks that \( S_{output} \) is "subtype" of \( S_{shared} \)
- Guarantees \( D_{output} : S_{shared} \)

Recursive XML Data

- Recursive functions support recursive data
  - XML Transformation
    User-defined functions
    "Signatures specify types of arguments & return values.
    Types enforced statically or dynamically.
    Same expressiveness as XSLT templates + parameters.

XQuery vs XSLT

- XSLT is primarily a language for describing XML transformation; XQuery is primarily a language to query XML data and documents.
- XQuery: XML \( \Rightarrow \) XML; XSLT: XML \( \Rightarrow \) {XML, HTML, text, ...}
- XSLT uses XML-based syntax; XQuery 1.0 doesn’t
- XPath is at the core for both, XSLT and XQuery.
- XSLT 1.0 turned W3C recommendation on November 16, 1999. XQuery 1.0 (as of Oct 29, 2004) is in Last Call Working Draft status. Many tools, APIs, and vendors have excellent support for XSLT. XQuery support is introduced by many vendors/toolkits; it has been rapidly improved and made complete.

XQuery vs XSLT

- XQuery 1.0 has a concept of user-defined functions, which can be modeled in XSLT 1.0 as named templates.
- XQuery 1.0 is strongly typed language, XSLT 1.0 is not.
- XQuery provides FLWOR expression for looping, sorting, filtering; XSLT 1.0’s xsl:for-each instruction (and XSLT 2.0’s for expression) allows to do the same.
- XQuery does not support all the XPath axes; XSLT does.
XQuery vs XSLT (cont.)

- XQuery: Reinventing the Wheel?
  http://www.xmlportfolio.com/xquery.html
- An interesting discussion:
  http://lists.xml.org/archives/xml-dev/200102/msg00483.html

XQuery vs. XSLT: Example

FOR $b IN document("bib.xml")//book
WHERE $b/publisher = "Morgan Kaufmann"
AND $b/year = "1998"
RETURN $b/title

<xsl:transform version="1.0"
xmllns:xsl="http://www.w3.org/1999/XSL/Transform">
  <xsl:template match="/">
    <xsl:for-each select="document("bib.xml")//book">
      <xsl:if test="publisher='Morgan Kaufmann' and year='1998'">
        <xsl:copy-of select="title"/>
      </xsl:if>
    </xsl:for-each>
  </xsl:template>
</xsl:transform>

Feature Summary

Implementor’s Perspective

- Interface: multiple implementation strategies
  - XSLT 2.0/XQuery 1.0: Custom Query engine
  - XPath 2.0: Translate into SQL/OQL/LDAP
  - XPath Data Model: Implement from scratch
  - DOM API: Build on existing storage system
  - SAX API: XML Parser
  - XQuery: Special-purpose Streams Processor
  - Xalan: XML Information Set
  - XML Toolkit: XML Document

  - XQuery Tutorial
XQuery

A strongly-typed, Turing-complete XML manipulation language
- Attempts to do static type-checking against XML Schema
- Based on an object model derived from Schema
Unlike SQL, fully compositional, highly orthogonal:
- Inputs & outputs collections (sequences or bags) of XML nodes
- Anywhere a particular type of object may be used, may use the results of a query of the same type
- Designed mostly by DB and functional language people
Attempts to satisfy the needs of data management and document management
- The database-style core is mostly complete (even has support for NULLs in XML!)
- The document keyword querying features are still in the works – shows in the order-preserving default model

"Iterations" in XQuery

A series of (possibly nested) FOR statements assigning the results of XPaths to variables

```
for $root in document("http://my.org/my.xml")
  for $sub in $root/rootElement,
    $sub2 in $sub/subElement, ...
```

- Something like a template that pattern-matches, produces a "binding tuple"
- For each of these, we evaluate the WHERE and possibly output the RETURN template
- document() or doc() function specifies an input file as a URI
- Old version was "document"; now "doc" but it depends on your XQuery implementation

Nesting in XQuery

Nesting XML trees is perhaps the most common operation
In XQuery, it’s easy – put a subquery in the return clause where you want things to repeat!

```
for $u in document("dblp.xml")/universities
  where $u/country = "USA"
  return <ms-theses-99>
    { $u/title }
    { for $mt in $u/../mastersthesis
      where $mt/year/text() = "1999" and ____________
      return $mt/title }
  </ms-theses-99>
```

XQuery’s Basic Form

- Has an analogous form to SQL’s SELECT...WHERE...GROUP BY...ORDER BY
- The model: bind nodes (or node sets) to variables; operate over each legal combination of bindings; produce a set of nodes
- "FLWOR" statement:
  for {iterators that bind variables}
  let {collections}
  where {conditions}
  order by {order-conditions} (the handout uses old "SORTBY")
  return {output constructor}

Two XQuery Examples

```
<root-tag>
  for $p in document("dblp.xml")/dblp/proceedings,
    $yr in $p/yr
  where $yr = "1999"
  return <proc> {$p} </proc>
</root-tag>
```

```
for $i in document("dblp.xml")/dblp/inproceedings[author/text() = "John Smith"]
  return <smith-paper>
    { $i/title/text() } </title>
    <key> { $i/@key } </key>
    { $i/crossref } </smith-paper>
```

Collections & Aggregation

In XQuery, many operations return collections
- XPaths, sub-XQueries, functions over these, ...
- The let clause assigns the results to a variable
Aggregation simply applies a function over a collection, where the function returns a value (very elegant!)

```
let $allpapers := document("dblp.xml")/dblp/article
return <article-authors>
  <count> ( fn:count(fn:distinct-values($allpapers/authors)) ) </count>
  { for $paper in doc("dblp.xml")/dblp/article
    let $auth := $paper/author
    return <paper> {$paper/title} </paper>
  } </article-authors>
```
Collections, Ctd.

Unlike in SQL, we can compose aggregations and create new collections from old:

```xml
<result> {
let $avgItemsSold := fn:avg(
    for $order in document("my.xml")/orders/order
    let $totalSold = fn:sum($order/item/quantity)
    return $totalSold)
return $avgItemsSold
} </result>
```

(* Slide by Zachary G. Ives, 2005)

Sorting in XQuery

- SQL actually allows you to sort its output, with a special ORDER BY clause (which we haven’t discussed, but which specifies a sort key list)
- XQuery borrows this idea
- In XQuery, what we order is the sequence of “result tuples” output by the return clause:

```xml
for $x in document("dblp.xml")/proceedings
order by $x/title/text()
return $x
```

(* Slide by Zachary G. Ives, 2005)

If Order Doesn’t Matter

By default:
- SQL is unordered
- XQuery is ordered everywhere!
- But unordered queries are much faster to answer

XQuery has a way of telling the DBMS to avoid preserving order:

```xml
unordered {
    for $x in (mypath) ...
}
```

(* Slide by Zachary G. Ives, 2005)

Distinct-ness

In XQuery, DISTINCT-ness happens as a function over a collection

- But since we have nodes, we can do duplicate removal according to value or node
- Can do fn:distinct-values(collection) to remove duplicate values, or fn:distinct-nodes(collection) to remove duplicate nodes

```xml
for $years in fn:distinct-values(doc("dblp.xml")//year/text())
return $years
```

(* Slide by Zachary G. Ives, 2005)

Querying & Defining Metadata

Can’t do this in SQL!

Can get a node’s name by querying node-name():

```xml
for $x in document("dblp.xml")/dblp/*
return node-name($x)
```

Can construct elements and attributes using computed names:

```xml
for $x in document("dblp.xml")/dblp/*,$year in $x/year,$title in $x/title/text(),
element node-name($x) {
    attribute {"year-" + $year} {$title }
}
```

(* Slide by Zachary G. Ives, 2005)

XQuery Summary

Very flexible and powerful language for XML
- Clean and orthogonal: can always replace a collection with an expression that creates collections
- DB and document-oriented (we hope)
- The core is relatively clean and easy to understand
- Turing Complete – we’ll talk more about XQuery functions soon

(* Slide by Zachary G. Ives, 2005)
**XSL(T): Bridge Back to HTML**

- XSL (XML Stylesheet Language) is actually divided into two parts:
  - XSL:FO: formatting for XML
  - XSLT: a special transformation language

- We’ll leave XSL:FO for you to read off www.w3.org, if you’re interested.
- XSLT is actually able to convert from XML → HTML, which is how many people do their formatting today.
  - Products like Apache Cocoon generally translate XML → HTML on the server side.

**A Different Style of Language**

- XSLT is based on a series of templates that match different parts of an XML document.
  - There’s a policy for what rule or template is applied if more than one matches (it’s not what you’d think!)
  - XSLT templates can invoke other templates
  - XSLT templates can be nonterminating (beware!)
- XSLT templates are based on XPath “match”es, and we can also apply other templates (potentially to “select”ed XPaths).
  - Within each template, we describe what should be output.
  - (Matches to text default to outputting it)

---

**An XSLT Stylesheet**

```xml
<xsl:stylesheet version="1.1">
  <xsl:template match="/dblp">
    <html>
      <head>This is DBLP</head>
      <body>
        <xsl:apply-templates/>
      </body>
    </html>
  </xsl:template>
  <xsl:template match="inproceedings">
    <h2><xsl:apply-templates select="author"/></h2>
    <p><xsl:apply-templates select="title"/></p>
    ...
  </xsl:template>
</xsl:stylesheet>
```

---

**Results of XSLT Stylesheet**

```xml
<dblp>
  <inproceedings>
    <title>Paper1</title>
    <author>Smith</author>
  </inproceedings>
  ...
</dblp>
```

---

**What XSLT Can and Can’t Do**

- XSLT is great at converting XML to other formats:
  - XML → diagrams in SVG; HTML; LaTeX
  - ...
- XSLT doesn’t do joins (well), it only works on one XML file at a time, and it’s limited in certain respects:
  - It’s not a query language, really
  - ... But it’s a very good formatting language.
- Most web browsers (post Netscape 4.7x) support XSLT and XSL formatting objects.
- But most real implementations use XSLT with something like Apache Cocoon.
- You may want to use XSL/XSLT for your projects – see www.w3.org/TR/xslt for the spec.

---

**Querying XML**

- We’ve seen three XML manipulation formalisms today:
  - XPath: the basic language for "projecting and selecting" (evaluating path expressions and predicates) over XML.
  - XQuery: a statically typed, Turing-complete XML processing language.
  - XSLT: a template-based language for transforming XML documents.
  - Each is extremely useful for certain applications!
