What is Al Pro?
Al Pro is an open-source data processing framework for Artificial Intelligence (AI) models. It supports major deep learning frameworks and Open Neural Network Exchange (ONNX).

Why use Al Pro, what is unique about it?
Al Pro has all the quintessential features to perform end-to-end data processing pipelines without a single line of code. Yes, you read it right, Al Pro’s working principle is configuration as code i.e. Al Pro empowers non-data-scientist to run prebuilt AI models without writing any code. Data pipelines are defined as directed acyclic graphs (DAGs).

How to use Al Pro?
Al Pro provides a Web User Interface (WebUI) for creating, managing and running data pipelines. Demos, tools, prebuilt models and configurations will be available from the website. Experts users can modify/update easy-entensible pluggable modules, custom models according to their needs and contribute in development of Al Pro.

Al Pro Data Pipeline Example

Al Pro’s Entities

We define entity as an abstract component responsible for either ingestion, transformation, addition, removal, or storage of data elements in the process of data flow. We present a brief introduction of each entity with example configuration.

**Data Source Entity.** Data pipeline always starts with a data source entity. Al Pro provides support for various types of data sources, such as (i) files, (ii) streaming APIs, and (iii) NoSQL Databases.

```json
{
  "alias": "Twitter Streaming Source",
  "api_key": "xxxxxxx",
  "uri": "http://example.com/api/data/"
}
```

**Filter Entity.** A filter entity controls data flow in data pipeline with conditional mathematical statement on data attributes. The output of a filter entity flows through separate paths in the DAG, or even discard certain data elements based on configuration.

```json
{
  "alias": "Language filter",
  "attribute": "lang",
  "value": "en",
  "condition": "=="
}
```

**Model Entity.** A model entity wraps an AI model with preprocessor and core model code. It has two sub-entities: (i) Preprocessor (ii) Core AI. Prebuilt model configurations can be obtained from model zoo.

```json
{
  "alias": "Sentiment model, custom",
  "input_attribute": "Text",
  "model_file_path": "uploads/sentiment.py",
  "model_name": "model",
  "module_class_name": "SentimentModel",
  "preprocessor_filename": "tweets_preprocessor.py",
  "preprocessor_methodname": "preprocess",
  "output_attribute": "sentiment"
}
```

**Data Sink Entity.** A data pipeline can have multiple storage entities that store processed data at different locations. Al Pro currently supports three types of storage entities: (a) Regular file, (b) Database (c) Standard I/O.

```json
{
  "db": "tweetsdb",
  "collection": "tweets",
  "alias": "Tweets MongoDB Connection",
  "host": "localhost",
  "type": "MongoDB",
  "port": 27017
}
```

**Custom Entity.** Experts can create custom entities for customized transformation of data elements. One example of such a custom entity that is included in Al Pro is geo-location mapping.
